Law of Large Numbers and Central Limit Theorem Example

Alexander Alexandrov

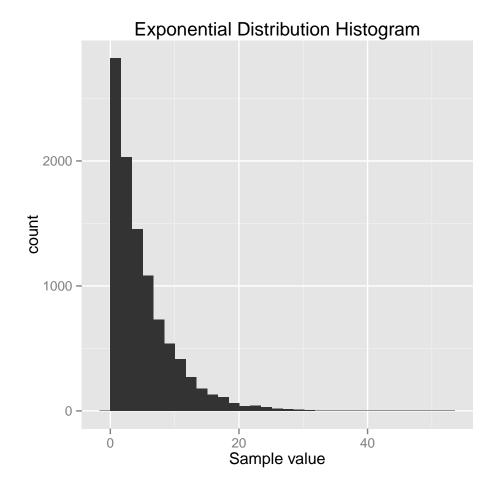

Overview

- The LLN states that the average limits to what it's estimating, the population mean.
- The CLT states that the distribution of averages of iid variables (properly normalized) becomes that of a standard normal as the sample size increases.
- This papre illustrates these lwas by the example based on the of exponential distribution.
- The mean of exponential distribution is 1/lambda and the standard deviation is also 1/lambda.

Simulations

Lets simulate exponentially distributed random variable.

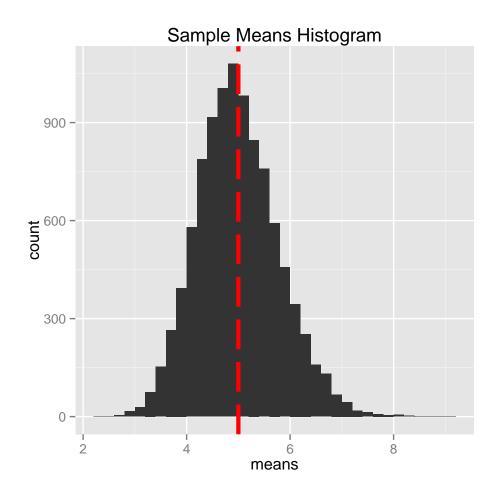

- Let sample size be equal to 40.
- Number of observations = 10000.
- Lambda (rate) = 0.2.

The samples variable contains iid observations (in it's rows). One observation for each row.

Sample Mean versus Theoretical Mean (LLN)

```
means <- rowMeans(samples)
g <- qplot(means, geom = "histogram", main = "Sample Means Histogram", binwidth = 0.2)
g <- g + geom_vline(xintercept = population.mean, colour = "red", linetype = "longdash", size = 1.5)
g</pre>
```

According to the LLN, the sample mean limits to the theoretical mean. **Theoretical** mean is showed by the **vertical red line**. And it's evident from this figure that sample mean is distributed around theoretical mean.

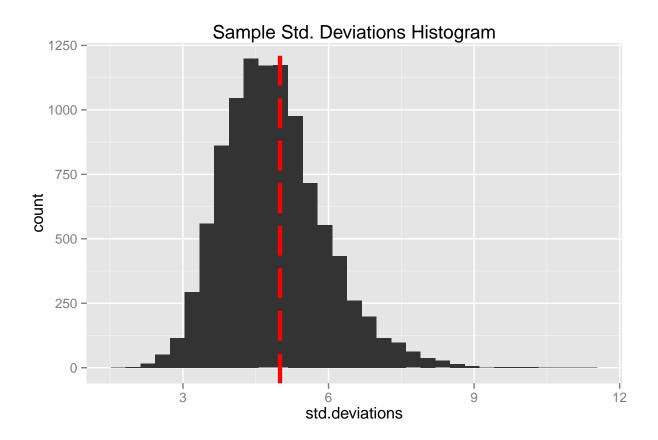

The relative difference between theoretical mean and sample mean:

```
paste(round(abs(mean(means) - population.mean) * 100, 1), "%", sep = "")
```

[1] "0.9%"

Sample Std. Deviation versus Theoretical Std. Deviation

```
std.deviations <- apply(samples, 1, sd)
g <- qplot(std.deviations, geom = "histogram", main = "Sample Std. Deviations Histogram")
g <- g + geom_vline(xintercept = population.sd, colour = "red", linetype = "longdash", size = 1.5)
g</pre>
```

According to the LLN, the sample std. deviation limits to the theoretical std deviation. **Theoretical** std. deviation is showed by the **vertical red line**.

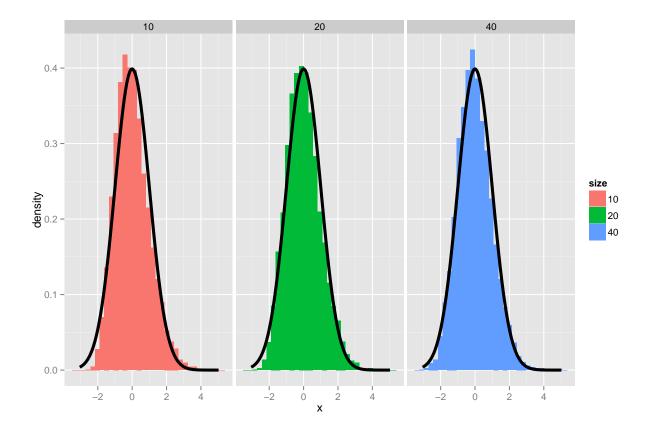

Distribution (CLT)

The CLT applies in an endless variety of settings - The result is that

$$\frac{\bar{X}_n - \mu}{\sigma / \sqrt{n}} = \frac{\sqrt{n}(\bar{X}_n - \mu)}{\sigma} = \frac{\text{Estimate - Mean of estimate}}{\text{Std. Err. of estimate}}$$

has a distribution like that of a standard normal for large n. The useful way to think about the CLT is that \bar{X}_n is approximately $N(\mu, \sigma^2/n)$.

- Let's simulate standart normal random variable.
- Let X_i be the smaple mean from the previous example (exponentially distributed random variable simulation).
- Then note that $\mu = E[X_i] = \frac{1}{\lambda}$.
- $Var(X_i) = \frac{1}{\lambda^2}$.
- SE = $\frac{1}{\lambda\sqrt{n}}$.
- For each observation take mean, subtract off μ , and divide by SE

According to the CLT, the larger the sample size, the closer sample param. distribution to the normal distribution.
